ABSTRACT

Population projections developed by the Pennsylvania Department of Education, 1970 to 2000, have been updated to report the latest information on fertility and mortality trends and migration within the State. Methology utilized closely resembles the cohort component procedure, with multiple regression analysis applied to historical information for mortality and fertility rate projections and net migration estimates involving recent economic and labor trends. Statistics are discussed with tables and graphs provided. It is stated tha the population projection for the State indicate modest growth between 1970 and 2000, with the number of children aged 5 to 19 years expected to decline rapidly between 1970 and 1985. Thereafter, it is expected that the State's population will begin to stabilize, increasing only slightly over the next 30 years. Appended material, 82 pages, discusses the computation of fertility rates and presents the following statistics: population projections for the State, 1970 to 2000; population projections for the counties, 1970 to 2000; and population projections for Pennsylvania's 10 State Board of Education higher education planning regions, 1970 to 2000. State Board of Education's Higher Education Planning Regions 96

Introduction

To facilitate planning, the Pennsylvania Department of Education in 1972 developed population projections to 1980 for the state, counties and major cities. At the time the department prepared those projections, a decline in the number of births was anticipated during the 1970s. Recent information on the actual number of births has indicated that there were even fewer births than had been anticipated.

At the same time (between 1970 and 1974), the death rates of persons over 64 years of age have decreased.

These changes indicated the need to revise population projections. Because long-range planning often extends to 20 or 25 years, the present population projections range to the year 2000. As with all projections, these are estimates based on past trends and present conditions but we hope the information will be useful to planners in their work.

I would like to take this opportunity to thank the author of this publication, John Senier, for a job well done.

Summary

Purpose: This report updates population projections for Pennsylvania so as to report the latest information on births, deaths and migration.

Procedure: The method used most closely resembles the cohort component procedure. Mortality and fertility rates were projected by applying multiple regression analysis to historical information. Net migration estimates by age, sex and county took into account 1960 to 1970 migration rates as well as recent economic and labor trends.

Results: The results indicate that Pennsylvania's population growth in the 1970s will be moderate, increasing about 270,000, or 2.3 per cent. Some of the major findings are:

- Pennsylvania's population may increase only about 5.3 per cent over the next 30 years.
- The decline in the number of live births since 1957 probably will abate and should increase slightly until around 1985.
- The reduction in the death rate for persons over 64 could result in an increase in the median age from 30.7 in 1970 to about 38.6 in the year 2000.
- The number of children between the ages of 5 and 19 probably will decline by 30 per cent between 1970 and 2000.
- The population aged 65 and over is projected to increase by about 865,000, or 48 per cent over the next 30 years.

Overview

Between 1790 and 1900 the population of Pennsylvania grew at a rate only slightly lower than that of the nation. During the 10-year period of 1900 to 1910, the state's population increased slightly more than the nation's (21.6 per cent versus 21.0 per cent). Thereafter, the rate of population growth declined rapidly in relation to the national rate of growth. By 1970 the state's population increased only 4.2 per cent from the previous census in 1960; the comparable national rate was 13.3 per cent.

This slower growth since 1910 can, in part, be explained by the state's birth rate. Between 1910 and 1970 Pennsylvania's birth rate was five to 15 per cent lower than the national average while the death rate for the state was five to 15 per cent higher than the nation's. A major reason for this discrepancy has been migration; since 1910 more people have left the state than have migrated to it. The nation, on the other hand, has experienced a consistent increase in its population due to migration.

The state's net loss of population due to migration has produced an imbalance in the age and sex composition of the population. Most of the people who traditionally migrate are between the ages of 20 and 34. Also, proportionately more men than women have migrated in the past. Since the prime childbearing age for women is between 20 and 34, the lower birth rate for the state is quite understandable. The loss of population between the ages of 20 and 34 due to migration has also raised the median age of the population. This fact, in itself, is the major reason for the slightly higher apparent death rate for Pennsylvania as compared to the nation.

The population projections for the counties, higher education planning regions and the state are revisions of projections which the Pennsylvania Department of Education made in 1972. The new projections are based on the latest information available on birth and death trends in Pennsylvania. The assumptions about future migration rates have also been changed in view of recent economic and labor trends.

The results indicate that Pennsylvania's population growth in the 1970s will be moderate--increasing 269,588, or 2.3 per cent. Because women born during the post-World War II baby boom are beginning to enter their prime childbearing years, births are projected to start increasing in the latter part of the 1970s. By 1985, however, the number of births are expected to decline. As a result, the state's population will begin to stabilize, increasing only slightly over the next 30 years.

Fertility Trends

Total Fertility Rate

Between 1960 and the present, the total fertility rate has decreased dramatically in the United States. In 1960 the Bureau of the Census estimated that each woman would have an average of 3.65 children (see Table 1) after having gone through the childbearing ages but by 1971 the total fertility rate dropped to 2.25 children. Based on one census projection (Series E), the rate will drop to 1.94 by 1975. Since a total fertility rate of 2.11 is required to attain zero population growth (that is, the number of births needed to replace the population who die)[1], it would appear that the population of the United States will stabilize by 1975. However, immigration accounts for some of the population increase. During the 1950s, an average of 251,000 persons immigrated to the United States each year. In the 1960s this number increased to about 333,000 each year.[2] Based on these trends, the United States is expected to experience a modest increase in population between 1970 and 1980.

The trend in Pennsylvania between 1960 and the present has been similar to that of the nation. In 1960 the Pennsylvania Department of Health estimated that each woman in the state would have an average of 3.35 children during her lifetime. By 1971 the total fertility rate for the state decreased to an average of 2.19 children per woman. In 1972 and 1973 the rate actually dropped below the 2.11 replacement rate. Considering that Pennsylvania experienced a net loss of 475,000 persons due to migration in the 1950s and 382,000 in the 1960s, the 1980 census may well show that the state's population did not increase in the 1970s.

Table 1 indicates that the anticipated total fertility rate (Bureau of the Census, Series E projection) will hold somewhere between 2.0 and 2.1 children in the 1980s and 1990s. Similarly, the total fertility rate for Pennsylvania in 1974 was 1.8--an increase of 0.1 over the 1973 fertility rate of 1.7. According to the 1970 census, about 93 per cent of all women aged 35 to 44 had been married sometime during their lives. The percentage for women aged 25 to 34 ever married was 88. Assuming that not all of these women bear children, that a small percentage of unmarried women bear children, and that the most common number of children per family is two, then the total fertility rate for Pennsylvania should stabilize between 1.7 to 1.9 children ever born per woman after having passed through the childbearing ages.

Age-Specific Fertility Rates

Table 2 shows that the decreases in the total fertility rate between 1960 and 1970 are attributable to a general decrease in every age-specific fertility rate. The decrease was greatest for women between the ages of 20 and 24 and over 29. The

national trends between 1960 and 1970 indicate that some women aged 20 to 24 delayed having children and that an increasing proportion of women over 29 years of age had no more children. The Bureau of the Census projects that these trends will continue until 1975. Thereafter, the fertility rate for women in each age group below 20 and over 34 is expected to stabilize. However, for women going through the prime childbearing ages, a slight upturn is projected in the age-specific fertility rates.

There appear to be similar declines in the age-specific fertility rates for Pennsylvania, with some exceptions. In 1972 and 1973 the age-specific fertility rate for women aged 25 to 29 was actually higher than for women aged 20 to 24. Traditionally, women in their early 20s have been the prime childbearers. This reversal may indicate a changing pattern in attitudes about when to have the first and last child. The declining age-specific fertility rates for women over 30 bear

out the assertion that fewer and fewer women are having children. The contention that more women are having their first child after reaching age 25 is supported by statistics published by the Pennsylvania Department of Health.[3] In 1965 women aged 25 to 29 had 13.4 per cent of all first-born children. By 1972 the women in that age group had 18.4 per cent of all first-born children.

Factors Related to the Decreasing Fertility Rate

In reviewing both the national and statewide decreases in the total fertility rate between 1960 and 1973, the obvious question is "What caused the decline"? The falling fertility rate cannot be attributed to any single factor; however, the cause must be rooted in the changing attitudes of the average family as to how many children, if any, it should have. One of the factors that undoubtedly influenced, and is still influencing this attitude is the fear of a population explosion which has been widely publicized since the mid-1950s. Environmentalists emphasized the need to curb the large population growth that took place between the mid-1940s and 1960s. Among the reasons they cited for halting the increase were depletion of natural resources and pollution of the environment.

Unfortunately, it is impossible to judge the degree of success environmentalists and demographers have had in altering the attitudes of the population on childbearing. Some people, citing the decline in the number of births and the total fertility rate after 1957, may argue that they have been successful. The counterargument is that during the depression of the 1930s, the total fertility rate, nationally, did not decrease. If individuals were unsuccessful in limiting the size of the family when economic necessity warranted it, how can arguments related to future overpopulation be successful?

It seems that some other factor was responsible for the sharp decline in the total fertility rate. This is not to say that the fear of a population explosion and the arguments of the environmentalists did not have an impact on the attitudes of the population. Similar arguments, however, have been in existence since 1798, when Malthus published his first work, "An Essay on the Principle of Population." The point is that people have been, and still are, concerned about the number of children they wish to have. Birth control in the form of abstention or contraception (developed in the early 1800s) has been available, but it was not until John Rock and George Pincus, working independently of each other, developed the oral contraceptive that planned parenthood became a workable reality. Although Enovid (produced by Searle Labs) was initially marketed in 1958 as a treatment for menstrual disorders, it soon gained wide acceptance and use as a contraceptive. At that time the pill was deemed safe and easy. Soon other drug manufacturers followed suit and began to market the synthetic estrogen, progestogen and other similar compounds. The public's acceptance of the pill was overwhelming, as illustrated by the volume of production and sales. Between 1958 and the

[3]Pennsylvania Department of Health, Bureau of Administration and Management, Natality and Mortality Statistics (Harrisburg, Pa.: Pennsylvania Department of Health, 1965 and 1972).

end of 1968 sales increased by 30 to 40 per cent each year.[4] By 1969 about nine million women in the United States were estimated to be taking the pill.

Then, in mid-1969, published research findings in England and the United States indicated that there was a high incidence of clotting disorders, or thromboembolic phenomena (TBE), associated with women taking oral contraceptives. Those findings were made public by the Dunlap Committee (Committee on the Safety of Drugs for Great Britain), which stated that the incidence of TBE might be four to eight times greater in women taking the pill than in those not taking the pill. In the United States, newspapers and periodicals, particularly monthlies such as Good Housekeeping, Ladies Home Journal and Redbook, published reports warning against the possible danger associated with taking the pill. Subsequently, the Senate Subcommittee on Health, under the direction of Senator Gaylord Nelson of Wisconsin, conducted hearings in January of 1970 on the dangers associated with oral contraceptives. Those hearings gave the opponents of oral contraceptives national attention. The Federal Drug Administration also sent letters to all physicians in the United States, advising them of the possible dangers involved in taking the pill.

Sales of oral contraceptives dropped off markedly among the six major producers in 1969 and remained in a depressed state until halfway through 1970, after which sales increased significantly. The increase in sales may have resulted from the Federal Drug Administration report made public in May of 1970. The news media and the public interpreted that report as indicating that it is no more dangerous to take oral contraceptives than it is to bear a child.

The reduced sales of the pill apparently had their effect. There were 100,000 more births in the United States in 1969 than in 1968. In 1970 the number of births increased from 3,600,000 (1969) to 3,731,000, but in 1971 they declined again to 3,559,000. Pennsylvania's experience was similar. The number of births in the state declined consistently after 1957, but in 1969 the decrease in births was negligible. Then, in 1970, the number of births increased from 185,046 (1969) to 192,154, and thereafter, births began to decline again.

This analysis indicates that the acceptance and use of the pill by the general public can adequately explain the declining total fertility rate. The drop in sales of the pill in 1969 and 1970 also seems directly related to the increase in births during those two years. To date, no other theory has satisfactorily explained the increase in the total fertility rate during those two years and the concomitant increase in births.

[4]Paul Vaughan, The Pill on Trial (New York: Coward-McCann, Inc., 1970).

Birth Trends

During the post-World War II years between 1946 and 1957, the number of resident live births for both the nation and Pennsylvania increased tremendously (see Figure 1). Most demographers now agree that the reasons for this large increase in the number of births were related to the following factors:

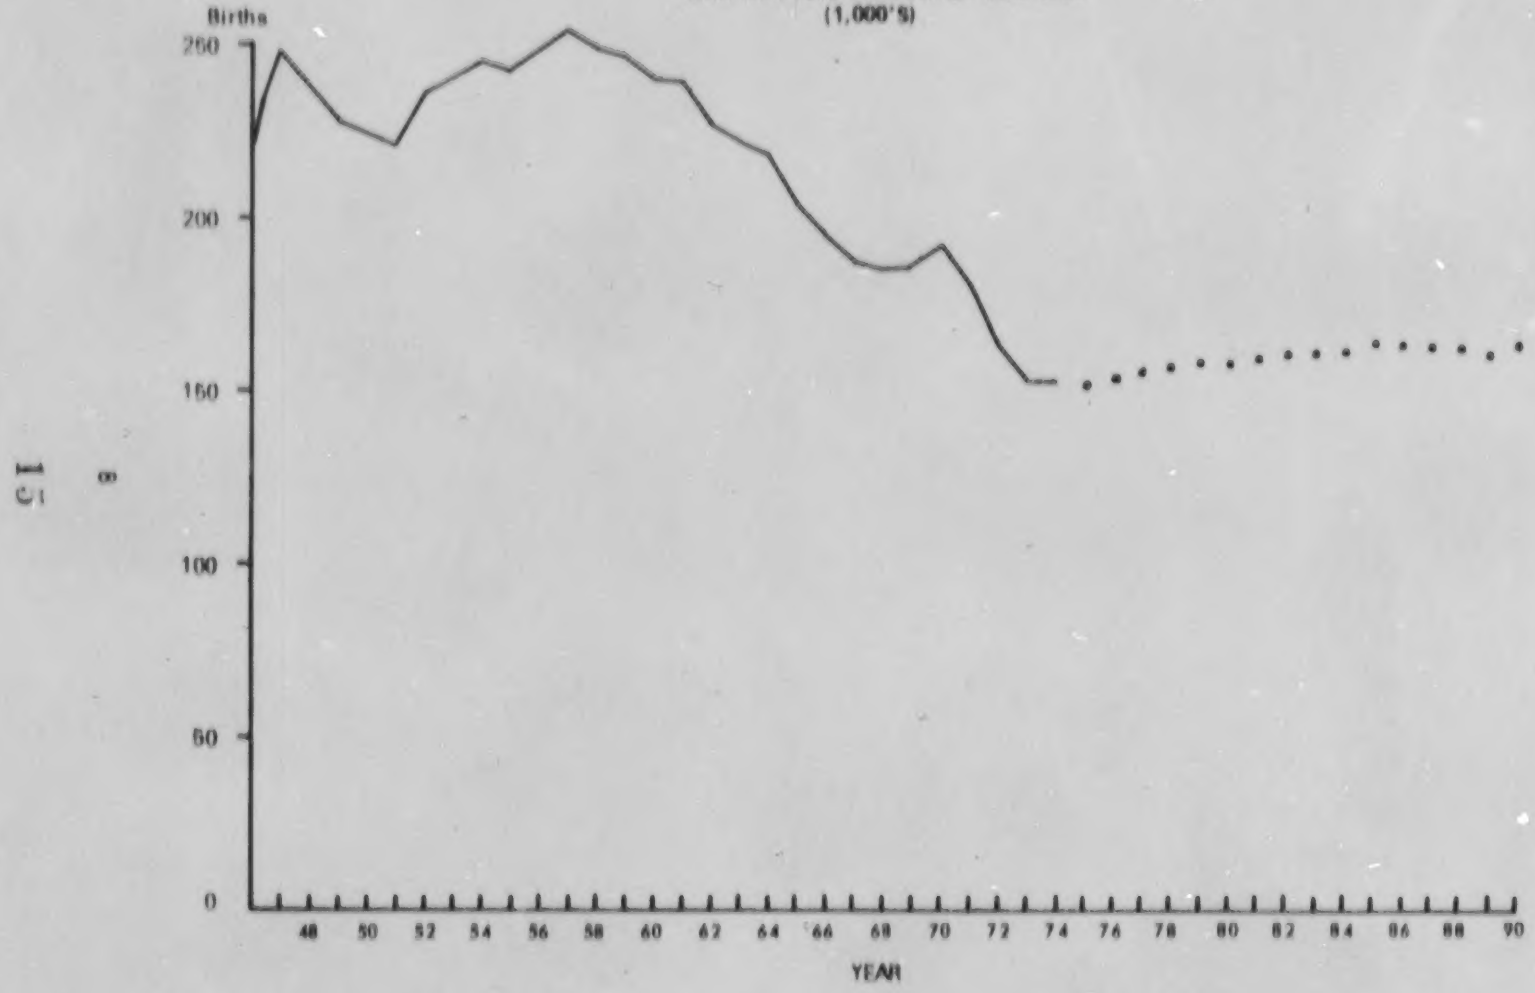
- End of World War II--returning soldiers and their mates started having children.
- Economic prosperity.
- Catching-up--people who delayed having children during the war years started having children.

In 1957 there were 254,997 resident live births in Pennsylvania, the largest number ever recorded for the state. Thereafter, the number of births declined steadily until 1969 and rose slightly in 1970. As pointed out in the discussion of fertility trends, the decline in the number of births was probably due to the increased acceptance and use of oral contraceptives.

As pointed out earlier, the slight increase in births in the nation for 1969 and 1970 is directly related to the decline in the sale and use of oral contraceptives as a result of findings published between the latter part of 1968 and the first few months of 1970 on the possible adverse effects of the pill.

After 1970 the number of births continued to decline in Pennsylvania. Preliminary data on the number of resident live births for 1974 indicate that the decline may soon halt, leveling off somewhere between 155,000 to 165,000 births during the latter 1970s and the 1980s. This assertion appears to be borne out in the previous discussion of fertility trends.

FIGURE 1
RESIDENT LIVE BIRTHS FOR PENNSYLVANIA
1946-1974 AND PROJECTED 1975-1990
(1,000's)



Mortality Trends

Although the number of resident deaths in Pennsylvania increased from 111,977 in 1940 to 126,483 in 1973, Pennsylvania's death rate decreased during those years. The rise in resident deaths in the state is due to two interrelated factors--rising median age and increases in the overall population. In 1940 there were 9,900,180 people with a median age of 29.1 living in Pennsylvania; by 1970 there were 11,793,909 people with a median age of 30.7. Considering that the age-specific mortality rate is lower for young persons than for older ones, the slight rise in the median age from 29.1 to 30.7 alone can account for the increase in the number of resident deaths.

A review of age-specific mortality rates (see Table 3) shows that there have been substantial decreases in the death rates for all age groups throughout the period between 1940 and 1970, particularly for children less than 5 years of age. By 1970 the death rate for those children declined by more than 60 per cent. The actual decrease in the death rates for persons aged 5 to 65 between 1940 and 1970 was also great. However, since the death rates for persons in those age groups were already low in 1940, the decrease has had only a minor effect in terms of the total population.

Declines in the death rate for persons over 64, on the other hand, have affected the total population figures. In 1940 slightly over one-fourth of all persons aged 85 and over were expected to die within a year; by 1970 only 17 out of 100 were expected to die within a year. Taken as a group, in 1970 it was anticipated that there would be about 156 fewer persons per 1,000 dying who were over 64 than would have died in 1940. A continuation of this trend can have far-reaching implications for Medicare-Medicaid, housing for the elderly and rest homes. A majority of persons over 64 years of age receive Social Security payments, and their number is anticipated to increase substantially throughout the 1970s and 1980s. As a result, workers will probably continue to see increases in the amount they will have to pay toward Social Security.

Table 3

Age-Specific Death Rates
for Pennsylvania: 1940 to 1970
(per 1,000 population in each age group)

Age Group	1970	1960	1950	1940
Under 1 year	21.4	25.2	31.5	55.1

Methodology and Assumptions

The system used to project population by age and sex for the state, higher education planning regions and the counties most closely resembles the cohort component methods. As in the cohort component methods, age-specific mortality and fertility rates were projected separately, but the method used to make those projections differs from the traditional or classical methods. To develop projected age-specific mortality rates for the state, the writer used multiple regression analysis to analyze the historical trends.

In preparing the projected total fertility rates, the researcher conducted a detailed analysis of the factors related to decreases and increases in the total fertility rate. That analysis indicated that the total fertility rate would probably stabilize between 1.7 and 1.9 children.

Because only complex methodologies can adequately determine future net migration, the researcher did not try to calculate projected net migration rates. Instead, the 1960 to 1970 net migration rates by age/sex were evaluated for the state and counties.[5] These rates were then compared to the 1950 to 1960 age/sex net migration rates. The comparison showed that although the age/sex net migration rates changed over the two decades, the proportion of the total effect attributable to each age/sex has generally remained stable. Accordingly, two basic assumptions are related to the projected age/sex net migration.

1. The net loss due to migration for the projected years will stabilize at about one-half the rate seen over the period 1960 to 1970.

2. The age-specific net migration ratio of males to females will be about the same for the projected years as it was between 1960 to 1970.

One of the major problems and sources of possible error in projecting future population lies in the calculation of births. One facet of this problem is the fact that births are generally calculated for calendar years while the decennial census is conducted starting April 1. Also, male and female births are not usually projected separately. Nationally, an average of 505 out of 1,000 births are males and 495 are females. Fluctuations in this ratio occur by chance and therefore are not predictable. For areas such as the Commonwealth of Pennsylvania or the populous county of Philadelphia, the discrepancy should be minor from year to year. An examination of the births in Pennsylvania between 1960 and 1973, however, reveals that the ratio of males to females per 1,000 births was 512 to 488. For smaller areas, the yearly fluctuations can be even greater. In Greene County, for example, the ratio of male to female births in 1973 was 476 to 524. Thus, any prediction of the number of male or female births for that county in 1973 would have been in error by about seven per cent strictly on the basis of fluctuations related to the male/female birth ratio.

---

[5]Senier, John, "Pennsylvania Population Growth and Net Migration" (Harrisburg, Pa.: Pennsylvania Department of Education, 1971).

Finally, births were projected using a total fertility rate of 1.8, which appears valid in view of historical trends observed over the last 17 years. In the actual calculations of the projected births, the total fertility rate was converted to the general fertility rate. The equations used to project births were

1. General Fertility Rate (GFR) = $\frac{\text{Total Fertility Rate}}{30}$

2. Births_y = No. Women 15-44$_y$ X GFR

3. $\text{Male Births}_y = \text{Births}_y \times .512$

   and $\text{Female Births}_y = \text{Births}_y - \text{Male Births}_y$

   where y = projected year

Based on the components detailed above, the researcher projected age cohorts by sex for five-year intervals with the following adjustments:

1. Age-specific mortality rates by sex were converted to age-specific survival rates (SR) by sex.

2. Age-specific net migration rates by sex were converted to age-specific yearly retention rates (RR) by sex.

The general form of the formula for projecting the age-specific population by sex is

For 1975, 1985 and 1995

$$P_{i,j,y+5} = P_{i-1,j,y} \times (SR_{i-1,j})^5 \times (RR_{i+1,j})^5$$

and

For 1980, 1990 and 2000

$$P_{i,j,y+10} = P_{i-1,j,y+5} \times (SR_{i-1,j})^5 \times (RR_{i,j})^5$$

where

P_i = age-specific population for the state or area

j = sex

y = year

SR = age-specific survival rate for the state

RR = age-specific retention rate for the state or area

The 0 to 4-year-old age group by sex was calculated by applying the appropriate survival and retention rates to the projected births for the number of years necessary before they became an entire age cohort. After the births for a five-year period became an age cohort, they were treated in the same way as any other cohort.

There is some error associated with using statewide methodologies to project a county's population. Although the researcher used county age/sex net migration rates to project county population, separate survival and fertility rates were not developed. Although yearly fluctuations should cancel each other out, errors may result from applying statewide survival and fertility rates to individual counties.

Results and Implications

The population projections for the state[6] indicate that Pennsylvania will experience only a modest growth between 1970 and 2000. In 1970 the census counted 11,793,909 persons. By 1980 the population is expected to increase by about 269,588 persons. Thereafter, the rate of population growth should decline even more. If the assumptions inherent within the projections hold true, the state's population should increase by about 160,594 between 1980 and 1990 and by about 194,826 between 1990 and 2000. By 2000 A.D. there may be some 12,418,900 persons in Pennsylvania. These figures indicate that the state will see a growth of about 625,000 people between 1970 and 2000.

Assuming that a particular population grows only through natural increase (births minus deaths) and migration, and that there will be a continuing loss due to migration and a stabilizing fertility rate, then the major factor contributing to the state's population growth is the anticipated reduction in the number of deaths. Consequently, the median age in Pennsylvania is expected to increase substantially (from 30.7 in 1970 to 32.2 by 1980 and 35.0 by 1990). If the assumptions hold true to the year 2000, the state's population may reach a median age of 38.6, an increase of almost eight years by the year 2000.

As a direct result of the decline in the number of births after 1957, the number of children aged 5 to 19 years is expected to decline rapidly between 1970 and 1985 and thereafter begin to stabilize.

Figure 2 shows that the number of people in that age group will decline from about 3.3 million in 1970 to about 2.3 million by the year 2000. Assuming there are no drastic changes in the percentage of children who attend school, the total basic education enrollments for the state may decline as much as 30 per cent by the year 2000.

Of course, the decrease in the number of births after 1957 has already had an effect on elementary school enrollments, which increased steadily in Pennsylvania until they peaked in 1967 at 1,716,252. Thereafter, the total number of enrollments started to decline. This downward trend will probably continue to at least 1984. The anticipated modest rise in births in the last half of the seventies may stabilize or slightly increase elementary enrollments in the last half of the eighties.

The decreasing number of births since 1957 has only recently begun to affect secondary school enrollments in the state. Total enrollments at that level increased until the 1974 to 1975 school year, when they fell by 10,058 students from the recorded high of 1,260,599 in the 1973 to 1974 school year. Based on the number of births projected, it appears likely that the total number of students enrolled in secondary schools may decline until 1991, subsequently secondary enrollments may stabilize or increase slightly.

The situation for the 20 to 24-year-olds in the state is quite similar to that for the younger ages, but is delayed.

FIGURE 2
PROJECTED POPULATION FOR PENNSYLVANIA
AGES 5-19
(Millions)

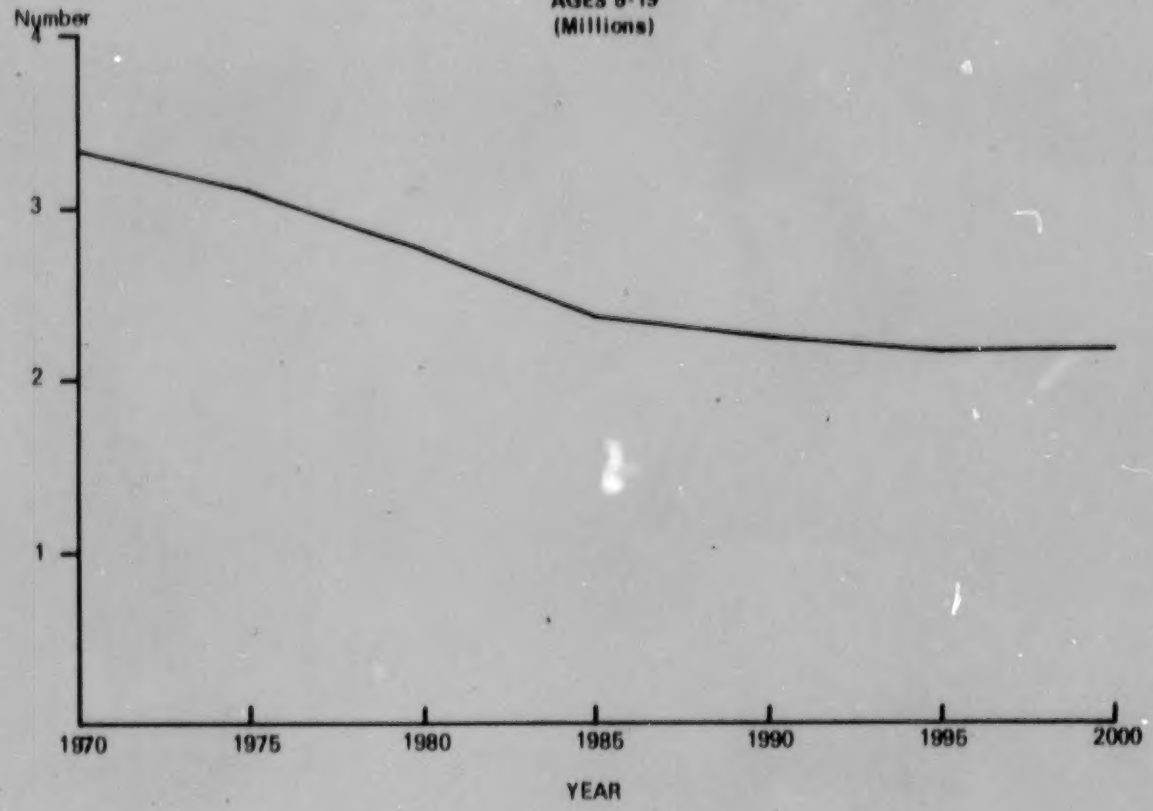

Figure 3 shows that the number of persons between the ages of 20 and 24 is anticipated to increase between 1970 and 1975, remain fairly stable until 1985 and thereafter decline rather sharply. By the year 2000 there will be 695,418 persons within the ages of 20 to 24 in Pennsylvania. Since there will be 1,082,711 persons in that age group in 1980, the decrease of 36 per cent between 1980 and 2000 is significant.

As pointed out previously, the major factor contributing to the projected population increases is the anticipated decrease in the death rate, especially among persons over 64 years of age. Historical data support this reduction in the death rate. Another possible factor in lower death rates among people over 64 years of age is Medicare/Medicaid.

Figure 4 shows that the number of persons between the ages of 65 and 74 is expected to increase from about 790,000 to almost 900,000 by the year 2000--an increase of almost 14 per cent. Assuming that a major proportion of those people are retired, taxpayers may face an added burden in the form of increased Social Security payments.

By itself, the projected increase in the number of persons aged 65 to 74 does not appear large, but when it is added to the projections of the number of persons aged 75 and over, the import of an aging population is clear.

The projections of the number of persons aged 75 and over, as represented in Figure 5, indicate that this age group will more than double in size between 1970 and 2000. In 1970, according to the census, there were 482,011 persons aged 75 and over in Pennsylvania. By the year 2000 there could be as many as 898,434 persons over 75. The impact of an increasing population over 64 years of age is already apparent to nursing homes and related facilities. According to information gathered by the Pennsylvania Department of Public Welfare, the total number of beds in homes for the aged, handicapped and infirm increased by 29 per cent between 1965 and 1974. Based on the population projections included in this report, similar, if not larger, increases in the number of available beds will be necessary in the near future.

Population projections for the 67 counties in the state indicate that there are large variations from county to county. Table 4 shows that the greatest population increases are projected for the counties concentrated in the southeastern section of the state, with the exception of Butler, Centre, Monroe, Pike, Snyder, Union and Wyoming counties. Except for Butler and Centre counties, however, the total population in those counties is small and has little effect on the overall state population.

Of major significance is the fact that 26 counties are expected to experience population declines by 1980 and that the number of counties experiencing a decline in population between the years 1980 to 1990 and 1990 to 2000 will increase to 33 and 32, respectively. Of the counties that are expected to decrease in population, only Dauphin and Philadelphia are not in the geographic area referred to as Appalachia. The major reason for the projected population decline in these two counties is the expected migration of persons from the city to suburban areas nearby.

The reader should exercise a certain amount of caution in reviewing population projections for the counties. As pointed out earlier, state mortality and fertility rates were used to prepare the county projections, so there may be a certain amount of error in the information presented in Appendix B.

Population projections for the 10 higher education planning regions are also included in this report (see Appendix D). The information for these 10 areas was obtained by aggregating the population projections for the counties included within each planning region. A map detailing the higher education planning regions is included in Appendix D so that the reader can see which counties are contained in each region.

APPENDIX A

APPENDIX A

COMPUTATION OF FERTILITY RATES

Zero Population Total Fertility Rate

Assuming that 495 out of 1,000 births are females and that about 95,744 out of 100,000 baby girls will survive to age 45, then

$$ZPFR = \frac{\text{Total Births}}{\text{Female Births X Survival Rate}}$$

$$= \frac{1{,}000}{495 \text{ X } .95744}$$

$$= 2.11$$

Because there is a slight difference in the ratio of male/female births and because some women die, each woman would have to have an average of 2.11 children in order to replace the population that dies.

General Fertility Rate

The general fertility rate can be derived in two ways. First, because it is defined in terms of the number of births per 1,000 women aged 15 to 44, the GFR can be calculated as follows:

$$GFR = \frac{\text{Births}}{\text{Women aged 15 to 44}} \text{ X } 1{,}000$$

Second, because the total fertility rate expresses the completed fertility of women after they have passed through the childbearing years (ages 15 to 44), the GFR can be thought of in the following way:

$$GFR = \frac{\text{Total Fertility Rate}}{30}$$

NOTE: Although a few women below 15 and over 44 years of age do have children, they account for less than one per cent of yearly births.

APPENDIX B
